ABSTRACT

Aim: The aim was to evaluate the potential influences of cytotoxic T-lymphocyte antigen-4 (CTLA-4) gene polymorphisms on breast cancer risk, the distribution of CTLA-4 single nucleotide polymorphisms (1661AG) in breast cancer patients and control subjects was investigated. Methods: In this case-control study, 100 patients with breast cancer as case group and 100 healthy participants as a control group were compared. Genotypes were determined by the polymerase chain reaction-restriction fragment length polymorphism method. Demographic characteristics of the study population, as well as tumor size, tumor grade and stage were collected in a questionnaire designed for this study. The collected data were statistically analyzed by SPSS-16.0 (SPSS Inc., Chicago, USA) predictive analytic software using the Chi-square test. Results: The mean age of women was 43.42 ± 13.1 years. The AA genotype was frequent in case group (43%) whereas the AG genotype was found more in the control group (69%). There was no significant relationship between the studied polymorphisms and the grade, stage and size of the tumor, nor between the studied polymorphisms and estrogen receptor, progesterone receptor and lymph node involvement (P > 0.05). Significant association between the studied polymorphisms and breast cancer metastases was found (P = 0.02). Conclusion: According to the results of the study, the AA genotype is associated with breast cancer, but none of the studied gene polymorphisms is associated with prognostic factors such as tumor stage, grade or size.

Key words: Breast cancer, cytotoxic T-lymphocyte antigen-4, polymorphism, prognosis

Introduction

Breast cancer is the most common cancer in women (30% of all cancers among women in developed countries), but is treatable if early diagnosis and treatment occur.[1] The incidence of breast cancer has constantly increased since 1940[2] and based on WHO reports, there is a 2% annual increase in breast cancer prevalence.[3] There are no exact statistics on the prevalence of breast cancer among the Iranian population (the source of our study); estimates show that Iran has moderate, but increasing, prevalence.[4] Both genetic and environmental susceptibilities are included in breast cancer etiology,[5] but the exact etiology has not been definitively identified. Current studies confirm the role of the immune system on the etiology of breast cancer.

It was shown that cancer cells provoke immune recognition, but the biologic importance of antitumor innate and adaptive responses, which are frequently detected in cancer-bearing hosts, remains incompletely understood.[9] The most considerable antitumor response is made by human cellular immunity mediated by T-lymphocyte and natural killer (NK) cells. It follows that variants of genes included in the regulation, and proliferation of T-lymphocyte and NK cells would be effective in predicting the risk of breast cancer. Cytotoxic T-lymphocyte antigen-4 (CTLA-4) is coded by a gene on chromosome 2q33. It is a member of the immunoglobulin super family, which transmits an inhibitory signal to T cells. CTLA-4 binds to B-7 on antigen-presenting cells, and polymorphism of CTLA-4 gene interferes with surface activity of B-7, preventing T-lymphocyte from activating.[10,11] In fact, CTLA-4 gene interferes with surface activity of B-7, preventing T-lymphocyte from activating.[10,11] In fact, CTLA-4 prevents immune response and its tumor-killing activity.[12] CTLA-4 gene is composed of 4 exons and possibly plays a significant role in diseases related to T cells. More than 100 single-nucleotide polymorphisms are recognized on the CTLA-4 gene. Among them, AG dysmorphisms, located on +49 of exon 1, could make amino acid (threonine into alanine) on CTLA-4 protein.[14] Current studies show that this polymorphism affects the ability of CTLA-4 to bind to B-7 cells and to activate T cells.[15,16] These surveys show that translocation of A allele to G allele on +49 zone decreases the role of...
CTLA-4 on T-cell responses,\textsuperscript{[15-18]} although there are contradictory reports on the relationship between +49 A to G polymorphisms and cancer development.

Higher expression of CTLA-4 is seen in persons with thiamine on zone -318 of \textit{CTLA-4} gene promoter or homogenous adenine on exon 1 of codon +49.\textsuperscript{[14]} There have been several studies on the relationship between polymorphisms on \textit{CTLA-4} gene and autoimmune diseases such as Graves, diabetes mellitus type one, lupus and Hashimoto thyroiditis\textsuperscript{[19-22]} and the tendency to develop cancer.\textsuperscript{[21-27]} Results of some studies show an inverse relation between polymorphisms of autoimmune diseases and malignancies on \textit{CTLA-4} gene. Alleles discovered in autoimmune diseases are not seen in malignancies or are related to a good prognosis of cancers. In a study in Iran, results suggested higher risk of breast cancer among AA and AG genotypes on +49 zone, but there was no difference between -318 CT and -1666 AG among case and control groups.\textsuperscript{[23,24]}

Considering the high prevalence of breast cancer and also some confirmed evidence of a relationship between \textit{CTLA-4} gene polymorphisms and breast cancer, we conducted this study to assess the relationship between \textit{CTLA-4} gene polymorphisms and both incidence and clinic pathologic features of breast cancer. The results of this study would help physicians to recognize the prognosis and risk ratio of patients with a high risk of breast cancer.

\textbf{Methods}

\textit{Study subjects}

The study group consisted of a total of 100 Iranian women with breast cancer and 100 healthy cancer-free control individuals. Informed consent was obtained from each subject, and each participant was then interviewed to collect detailed information on demographic characteristics such as sex and age. Some clinic pathologic features of breast cancer patients, such as tumor size, lymph node involvement, tumor type, and estrogen receptor (ER), were also obtained from their medical files [Table 1].

Patients were recruited between February 2013 and October 2014 at the Shahid Sadughi Hospital and Cancer Hospital, Yazd, Iran. Control subjects were cancer-free individuals, and they were randomly selected from the same regions and the same time period as the patients were collected. The selection criteria included no individual history of breast or other cancers.

This study was approved by the Ethics Committee of Shahid Sadoughi University of Medical Sciences, Yazd, Iran. A written informed consent was taken from all patients.

Data are presented as \textit{n} (%). \textit{CTLA-4}: Cytotoxic T-lymphocyte antigen-4

\textbf{Polymorphism genotyping}

Peripheral blood (5 mL) was collected from subjects after informed consent was obtained. Genomic DNA was extracted from peripheral blood using the DNA extraction kit (BioFlux, cat: BSC 06M1, Hangzhou, Bioer Technology Co., Ltd, China).

Genotyping was performed by polymerase chain reaction (PCR)-restriction fragment length polymorphism method. The polymorphic region was amplified by PCR using the following primers: \textit{(forward)} 5’-CTAAGAGCATCCGCTTGCACCT-3’ and \textit{(reverse)} 5’-TTGGTGTGATGCACAGAAGCCTTT-3’ in a 25 \textmu L reaction solution containing 0.3 \textmu g of genomic DNA, \times 1 PCR buffer, 0.3 mmol/L MgCl\textsubscript{2}, 0.2 mmol/L dNTPs, 2 U tag DNA polymerase and 0.1 \textmu mol/L of each primer.

The following PCR program was run: 94 °C for 4 min, 30 cycles of 94 °C for 30 s, 58 °C for 30 s and 7 °C for 45 s. Final extension was carried out at 72 °C for 5 min. The lengths of the PCR products were 486 bp (1661AG).

The PCR products were digested with restriction enzymes TruII (MseI) according to the manufacturer’s instructions (Thermo Scientific Fermentas, USA) and
analyzed by 2% agarose gel electrophoresis. The cut site for Tru1I (MseI) was 5’-TTAA-3’.

The digested fragments in 1661AG were 139 and 347 bp. Presence of the A allele was recognized by detecting digested 347 and 139 bp fragments on gel, and the G allele by detecting intact primary 486 bp band [Figure 1]. Comparisons of genotype and allele frequencies in cases and controls were assessed by Chi-square and t-test using SPSS-16.0 (SPSS Inc., Chicago, USA). Statistical software and statistical significance were set at $P \leq 0.05$. The odds ratio and 95% confidence interval were also calculated.

**Results**

A total of 100 women with breast cancer and 100 healthy controls were enrolled in this study. Mean age of the case group was 48.92 ± 9.85 years and of the control group was 37.92 ± 13.67 years ($P < 0.001$; $t$-test). This study was done in patients who presented at Shahid Sadaghi Hospital and Cancer Hospital, Yazd, Iran. The grade, stage and size of the tumor in the case group are shown in Table 1. About 73.3% of patients had grade one tumors, and about 75% had stages 1 and 2 tumors. Tumor size in more than 60.9% of patients was $\leq 2$ mm.

Polymorphisms of $CTLA-4$ gene are shown in Figure 2. There is a significant relationship between groups according to gene polymorphisms ($P = 0.03$). Frequency of AA polymorphisms in the case group is higher than in controls whereas AG polymorphisms are more frequent in the control group.

Table 1 shows polymorphisms according to tumor stage. There is no significant difference among study groups according to tumor grade ($P = 0.21$). Also there was no relationship between polymorphism and tumor stage ($P = 0.50$) and tumor size ($P = 0.50$).

Considering the difference in mean age between the two study groups, we analyzed polymorphisms of $CTLA-4$ gene in all participants according to age groups of under or over 40 years, but found no significant difference ($P = 0.30$) [Table 1]. We determined that the age difference between the two groups had no confounding effect on the study results.

Analysis of metastasis showed that there is a significant relationship between $CTLA-4$ gene polymorphism and metastasis. Patients with AA genotype had higher rates of metastasis ($P = 0.02$) [Table 1].

Analysis also showed no relationship between $CTLA-4$ gene polymorphisms and ER ($P = 0.49$), progesterone receptor ($P = 0.15$) and lymph node involvement ($P = 0.53$) [Table 1].

**Discussion**

There is increasing attention to the relationship between several genes’ polymorphisms and polygenetic diseases such as hypertension, diabetes, and various malignancies.[28] T cells and NK cells have a substantial role in working against tumors.[29] T-lymphocyte, especially T killer cell, is the most important in defending cells against tumors. $CTLA-4$ molecule expresses on T-lymphocyte as an inhibitor and plays different roles in T-cell activity. It could inhibit amplification of T cells or even induce apoptosis of activated T cells.[30] $CTLA-4$-mediated suppression of tumor immunity has been previously reported.[31] Several studies have demonstrated the effect of $CTLA-4$ blockade in enhancing immunity to tumors.[14-16] There are some studies on the relationship between $CTLA-4$ gene polymorphisms and breast cancer, but results were contradictory.[31] In order to clarify the role of genetic variants of $CTLA-4$ gene in immune suppression of patients with cancer, the distribution of $CTLA-4$ gene single nucleotide polymorphisms (1661AG), in breast cancer patients and

control subjects, were investigated and their associations were assessed with prognostic factors. The present case control study was done to determine possible relationships between AA, AG and GG polymorphisms of CTLA-4 gene and breast cancer-related factors. Results revealed that the frequency of AA and AG genotypes in breast cancer patients is higher than in controls, while AG genotype is more frequent in healthy controls. These results confirm the findings of two other studies in Iran[23] and China,[32] which found GG genotype is more frequent in breast cancer patients. However, Erfani et al.[34] did not find any difference between their study groups in terms of AG genotype. Another study in China suggested that AG genotype is more prevalent in breast cancer patients.[33] Furthermore, Sun et al.[15] reported that T cells with AA genotype are less active than those with GG genotype, and AG is related to different cancer incidence in humans.

The results of our study did not find any relation between AA, AG and GG genotypes with respect to tumor stage, grade, receptors or lymph node involvement. These results are in agreement with results of Wang et al.,[16] who found no significant relationship between AG genotype and tumor size and lymph node involvement. Erfani et al.[34] found a relationship between AA genotype and lower lymph node involvement and higher ER expression, but Ghaderi et al.[23] found that AA genotype is related to higher rates of lymph node involvement and tumor size; these findings are different from our findings. Bi et al.[34] in his study reported that CTLA-4 expression is higher in stage 2 than stage 3 patients. There are also some other studies, which revealed that CTLA-4 gene polymorphisms are related to higher stages and lymph node metastasis,[6,32] which is not consistent with our study. According to age, in our study and also in the Bi et al.[34] there was no relationship between CTLA-4 gene polymorphisms and age.

Li et al.[32] found a relationship between all CTLA-4 gene polymorphisms with estrogen and progestrone receptors. Also, Erfani et al.[24] detected a relationship between AG genotype and ER expression, which was not consistent with our findings.

One of the limitations of our study is the failure to take into account risk factors such as age at menarche, menopausal status, and environmental factors. It is important to investigate the interaction between single-nucleotide polymorphisms and these factors on the risk of breast cancer in a larger sample size in further studies.

Based on our study, there is a relationship between CTLA-4 gene 1661AG polymorphisms and incidence of breast cancer, but these polymorphisms are not effective for prognosis. Considering the controversial reports on this issue, more studies are needed with larger sample size. Also, a critical review and possible meta-analysis of present studies are needed to make an exact estimation of the results of current studies.
